

Between-group spread: real human diversity against a synthetic condition that never left the noise floor

Human conditions, full precision
350 items, 6 demographic cells

Like-for-like: one draw per group
15 items, Asian-Woman vs White-Man

Left: full-precision human spread on all 350 items, against a null that shuffles rater-to-group labels at fixed group sizes.

Right: every condition reduced to the LLM's own estimator (one draw per group) so they are comparable. Both LLM conditions fall inside the band of pure sampling noise measured from repeating a single persona; the human condition lies above it in 96.9% of bootstrap draws.
